Although the term "disproportionation" is commonly used by chemists to describe inter-bubble gas diffusion within foams, it is often referred to as Oswald ripening, which was originally used to define the evaporation–condensation mechanism in two-phase separation of binary alloys.

### Processes in foaming (Chapter 4) - Bubble and Foam Chemistry

The second method involves artificially producing gas bubbles by physical methods (e.g. by nucleation or electrolysis) or chemical methods, which are commonly exploited in the production of polymer foams and involve the use of so-called blowing agents. These are chemical compounds that decompose or react to produce gas bubbles.

### Generation of bubbles and foams (Chapter 5) - Bubble and ...

Displacing the gas from inside the bubble obviously then causes it to collapse and ruins foam. Non-hydrophobic FNAs (such as alcohol and glass cleaners etc.) will generally cause foam collapse by preventing the bubbles from sticking together. Foam Positive agents (FPAs) basically work by enhancing all of the things we discussed previously.

Synopsis. This indispensable guide will equip the reader with a thorough understanding of the field of foaming chemistry. Assuming only basic theoretical background knowledge, the book provides a straightforward introduction to the principles and properties of foams and foaming surfactants. It discusses the key ideas that underpin why foaming occurs, how it can be avoided and how different degrees of antifoaming can be achieved, and covers the latest test methods, including laboratory and ...

The properties of each foam largely depend on the fat content of the milk used to make it, but a big difference between cold agitation and steam injected foams is the distribution of the air bubbles. Steam injected foams tend to be "airier" on top and thicker/more liquid towards the bottom of the container, while agitated forms are more ...
